

be used. Interactive views of meshes, fields and solid bodies are enabled by PyVista (Sullivan & Kaszynski, 2019). The capabilities of FElupe may be enhanced with additional Python packages, e.g. meshio (Schlömer, 2024), matadi (Dutzler, 2024b), tensortrax (Dutzler, 2024c), hyperelastic (Dutzler, 2024a) or feplot (Mohamed ZAARAOUI, 2023).

## Features

The essential high-level parts of solving problems with FElupe include a field, a solid body, boundary conditions and a job. A field for a field container is created by a mesh, a numeric region, see Figure 1.

Figure 1: Schematic representation of classes needed to create a field container.

In a solid body, a constitutive material formulation is applied on this field container. Along with constant and ramped boundary conditions a step is created. During job evaluation, the field values are updated in-place after each completed substep as shown in Figure 2.

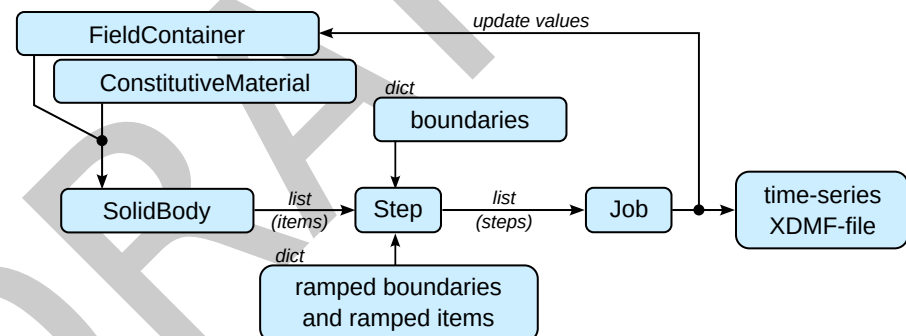

Figure 2: Schematic representation of classes needed to evaluate a job.

For example, consider a quarter model of a solid cube with hyperelastic material behavior subjected to a uniaxial elongation applied at a clamped end-face. First, a meshed cube out of hexahedron cells is created. A numeric region, pre-defined for hexahedrons, is created on the mesh. The appropriate finite element and its quadrature scheme are chosen automatically. A vector-valued displacement field is initiated on the region and is further added to a field container. A uniaxial load case is applied on the displacement field to create the boundary conditions. This involves setting up symmetry planes as well as the absolute value of the prescribed displacement at the mesh-points on the right-end face of the cube. The right-end face is clamped, i.e. its displacements, except the components in longitudinal direction, are fixed. An isotropic hyperelastic Neo-Hookean material formulation is applied on the displacement field of a solid body. A step generates the consecutive substep-movements of a selected boundary condition. The step is further added to a list of steps of a job. After the job evaluation is completed, the maximum principal values of logarithmic strain of the last completed substep are plotted, see Figure 3.

```
import felupe as fem
```

```
region = fem.RegionHexahedron(mesh=fem.Cube(n=6))
field = fem.FieldContainer([fem.Field(region, dim=3)])
solid = fem.SolidBody(umat=fem.NeoHookeCompressible(mu=1, lmbda=2), field=field)
boundaries, loadcase = fem.dof.uniaxial(field, clamped=True)

move = fem.math.linsteps([0, 1], num=5)
step = fem.Step([solid], ramp={boundaries["move"]: move}, boundaries=boundaries)
job = fem.Job(steps=[step]).evaluate()

solid.plot("Principal Values of Logarithmic Strain").show()
```

**Figure 3:** Final logarithmic strain distribution of the deformed hyperelastic solid body at  $l/L = 2$ . The undeformed configuration is shown in transparent grey.

Any other hyperelastic material model formulation may be used instead of the Neo-Hookean material model given above, most easily by its strain energy density function. The strain energy density function of the Mooney-Rivlin material model formulation, as given in Equation 1, is implemented by a hyperelastic material class in FElupe with the help of `tensortrax` (bundled with FElupe).

$$\psi(C) = C_{10} (\hat{I}_1 - 3) + C_{01} (\hat{I}_2 - 3) \quad (1)$$

```
import tensortrax.math as tm

def mooney_rivlin(C, C10, C01):
    I1 = tm.trace(C)
    I2 = (I1**2 - tm.trace(C @ C)) / 2
    I3 = tm.linalg.det(C)
    return C10 * (I3**(-1/3) * I1 - 3) + C01 * (I3**(-2/3) * I2 - 3)

umat = fem.Hyperelastic(mooney_rivlin, C10=0.5, C01=0.1)
solid = fem.SolidBody(umat=umat, field=field)
```

## Examples

The documentation of FElupe contains interactive tutorials and examples for simulating the deformation of solid bodies. Resulting deformed solid bodies of selected examples are shown in Figure 4. Computational results of FElupe are used in several scientific publications, e.g. (Dutzler et al., 2021), (Buzzi et al., 2022) and (Torggler et al., 2023).

**Figure 4:** Equivalent stress distribution of a plate with a hole (top left). Shear-loaded hyperelastic block (top middle). Endurable cycles obtained by local stresses (top right). Multiaxially loaded rubber bushing (bottom left). Rotating rubber wheel on a frictionless contact (bottom middle). A hyperelastic solid with frictionless rigid contacts (bottom right).
